Abstract

Thermodynamic functions are normally calculated experimentally through studying the effect of temperature on the equilibrium constant. Such studies may face experimental errors, they may require the consumption of expensive chemicals, in addition of being time consuming. The development of computer science and programming facilitated the theoretical study of such project. In this work the determination of pKa of several Schiff bases are achieved by statistical analysis using SPSS program (V.12) and by employing parameters based on quantum mechanically derived method. The Chem. Office program (V.12,2010) is used for achieving these studies. The density functional theory (DFT) is applied as an ab initio method, using the method of (B3LYP) at basis set (3-21G). The theoretical pKa values were determined by several derived equations at several temperatures (20,30,40,50, and 60 °C). These equations were obtained from applying multi-parametric regression analysis based on parameters derived from DFT method. The calculated pKa were highly consistent with the practical values in terms of R² and SE. These consistency improved as temperature increased from 20-60°C. The best agreement between pKa_(calc) and pKa_(exp) are seen

Introduction

Computational chemistry is an important and commonly used topic in calculating many chemical functions in various fields of chemistry. It was used for calculating the chemical shift of C-13 and N-15 NMR, and in calculating the pK values of many organic compounds. Schiff rules have received great attention in this field. Schiff's bases are compounds of great importance [1]. Their ease of preparation, the presence of variety of substituents, and the imine group (C=N) in their structures, attracted researchers to use it in various industrial applications such as anti-corrosion inhibitors, the manufacture of polymers and dyes [2]. In addition, it has wide scope of biological activities. They were used as selective and sensitive reagents in estimating metals by formation of colored complexes with a number of metal ions [3].

The pKa (dissociation constant of acid) is a valuable chemical function. It helps in estimating the ionization behavior of various kinds of compounds such as Schiff's bases[4]. The extent of ionization of these compounds is determined in aqueous solution that gives the hydrogen ion with the conjugated base for the ionized compound. One of the most important uses of pka values is to estimate the stability, dispensation, and accommodating the drug in the body. The pka function could also be used as an indication of the acidity strength. The pKa value is calculated mathematically by the negative value of logarithm (Ka). The strength of the acidity is inversely proportional to the value of pka although there are many practical methods used to estimate pKa values, the theoretical methods are characterized by their ability to give a quantitative description for the chemical variations, while practical methods are often limited to providing a qualitative description only [5-6].

The pKa value is affected by two factors, electronic and geometrical. The first factor is represented by inductive and mesomeric effects, while the spatial congestion representing the steric effect. Since such factors can be estimated using quantum mechanical methods, this encouraged many researchers in the field to work in this path [7].

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

Method and Calculation

This work is carried out by gathering experimental pKa values for a number of Schiff bases from the literature and used for achieving this research. Two programs, the Chem. Office (V12, 2010) employing the density functional theory (DFT) to undergo the parameters determination which will be used to estimate the pKa by correlation using regression analysis by (SPSS program V.2011). Parameters used as descriptors of the electronic and steric factors such as electronic density, charges, the value of the total energy of the molecule, the energies of the molecular orbitals HOMO, LUMO and other variables will be mentioned and calculated later [6,7].

Simple regression analysis (eq.1) is performed between pKa values with each of the proposed variables. Depending on the results obtained, then multiple linear regression analysis (MLRA) (eq.2) is achieved. Mathematical relationship is derived from variables determined by applying DFT method.

$$Y = b + aX \quad (1)$$

$$Y = b + a_1X_1 + a_2X_2 + a_3X_3 + \dots + a_nX_n \quad (2)$$

Where Y is representing the pKa as a dependent variable, X_1, X_2, \dots, X_n , are independent parameters and calculated by DFT method, a_1, a_2, \dots, a_n , are coefficients $X_1, X_2, X_3, \dots, X_n$ respectively, and b is a reference value. The success of regression and making the correct choice of parameter is indicated by correlation coefficient ($R^2=1$) close to unity, standard error (SE) less than 5% of the experimental error and the consistency with the physical meaning of the subject under consideration [8].

The pKa values of the compounds under study are estimated. The experimental pKa ($pKa(exp)$) are then compared with the calculated by equations (3-to-7) which will be derived later by regression analysis. The calculated pKa is compared to their experimental results. Then the thermodynamic functions are estimated theoretically under the same practical conditions of

solvent and temperatures. Regression analysis is carried out at each temperature, pKa and thermodynamic functions are calculated and compared with practical values.

Results and Discussion

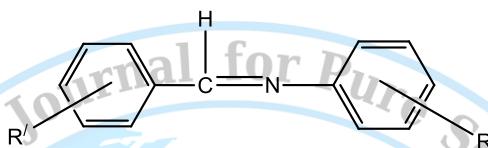

Figure1: Structures of the considered compounds in this study

Table 1: Substituents and the experimental values of pKa of the Schiff bases selected from the literature [9] for achieving this study

COMP.NO	Substituents	
	R'	R
1	P-OH	P-NH ₂
2	P-OCH ₃	P-NH ₂
3	P-OCH ₃	m- NH ₂
4	o-NH ₂	o-OH
5	o-NH ₂	m-OH
6	o-NH ₂	p-OH
7	o-F	o-OH
8	o-F	m-OH
9	o-F	p-OH

According to the figure 1, the pKa values are affected by electronic and steric effects and since such parameters could be determined by quantum mechanical methods. The development of computer science, technology and programming facilitate such studies which attracted many researchers in the field and the interest for such calculations is increased [10]. When looking at the literature, a wide scope of various theoretical application can be seen. In this work the density functional theory (DFT) has been applied to achieve this study. It is believed that the DFT method could be the best choice to estimate the pKa by this method of calculation.

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

Ra'ed T. Gh. Al-Abady, Fedaa Hasan Meire Altaiea and Emad A. S. Al-Hyali

This method of calculation is aimed to estimate the values of pKa of the selected compounds for doing this work by deriving theoretical equations from statistical analysis depending on the calculated parameters by employing DFT method.

The parameters used as descriptors for achieving the statistical analysis are determined by the application of the DFT method employing the method of B3LYP at bases set 3-21G. Several types of parameters are calculated such as kinetic energy (KE), Total energy (TE), potential energy (PE), energy of Highest Occupied Molecular Orbital (HOMO), energy of the Lowest unoccupied Molecular Orbital (LUMO), lowding charge of nitrogen atom of the imine bond (NL) and Mullikan charge of imine bond (NM), In addition to those, lowding charge of O (OL), Mullikan charge of O (OM), length of C=N bond (C=N) and dipole (1),(2) and (3). The values of these parameters are calculated at temperatures 20°C, 30°C, 40°C, 50°C and 60°C as presented in Tables (2-6) respectively. The aim of determining these values at different temperatures is to derive various equations for calculating the thermodynamic functions theoretically [11,12]. Looking at the values in tables (2-6) it can be seen clearly those the values of parameters stay constant except the values of the pKa.

The relation among the parameters themselves and with values of the pKa was investigated by applying simple regression (eq.1) at different temperatures. The results obtained are listed in tables (7-to-11). The results of the correlation are listed in tables (7-to-11). These results showed variation in the correlation coefficients when studying the relation between the pKa values with T.E, K.E, energy of HOMO, LUMO, Charges and dipole 1,2,3. The rest of relations stay constant i.e., not affected by temperature. In order to derive an equation at each temperature to calculate the pKa. MLRA is used for this purpose. Several attempts were tried table (12) until the best set of parameters in terms of the correlation coefficient (R^2) and standard error (SE) were obtained at each temperature table (13)

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

*Res= pKa(exp)-pKa(calc)				

The results obtained from the MLRA was carried out at 20-60°C and by using ethanol as solvent in simulation to the experimental conditions are listed in table (13). These results were formulated as five linear equations at five different temperatures (eqs. 3-7) and used for the calculation of the theoretical pKa values [15-17]

$$pK_a = -213.790 - 4.820 \times 10^{-4} \times TE - 25.951 \times N_L \text{ of } NH_2 - 21.932 \times O_L \text{ of } OH \dots \dots (3)$$

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

Ra'ed T. Gh. Al-Abady, Fedaa Hasan Meire Altaiea and Emad A. S. Al-Hyali

$$pK_a_{at30C} = -406.617 - 8.835 \times 10^{-4} \times TE - 21.778 \times N_M \text{ of } NH_2 - 24.744 \times O_M \text{ of } OH \dots\dots\dots(4)$$

$$pK_a_{at40C} = -23.652 - 2.532 \times 10^{-4} \times TE - 70.373 \times N_L - 70.432 \times C = N \dots\dots\dots(5)$$

$$pK_a_{at50C} = -120.512 - 2.685 \times 10^{-4} \times TE - 64.025 \times N_L + 0.095 \times Dipol2 \dots\dots\dots(6)$$

$$pK_a_{at60C} = -127.607 - 2.799 \times 10^{-4} \times TE - 76.529 \times N_L + 0.134 \times Dipol2 \dots\dots\dots(7)$$

The above equations (3-7) were employed to calculate the value of pKa at 20,30,40,50 and 60°C respectively. Comparison between calculated pKa with the experimental values are given in Table (14) and plotted in figure (2). This comparison showed good agreement between the experimental and calculated pKa; better correlation is indicated in terms of R^2 and SE.

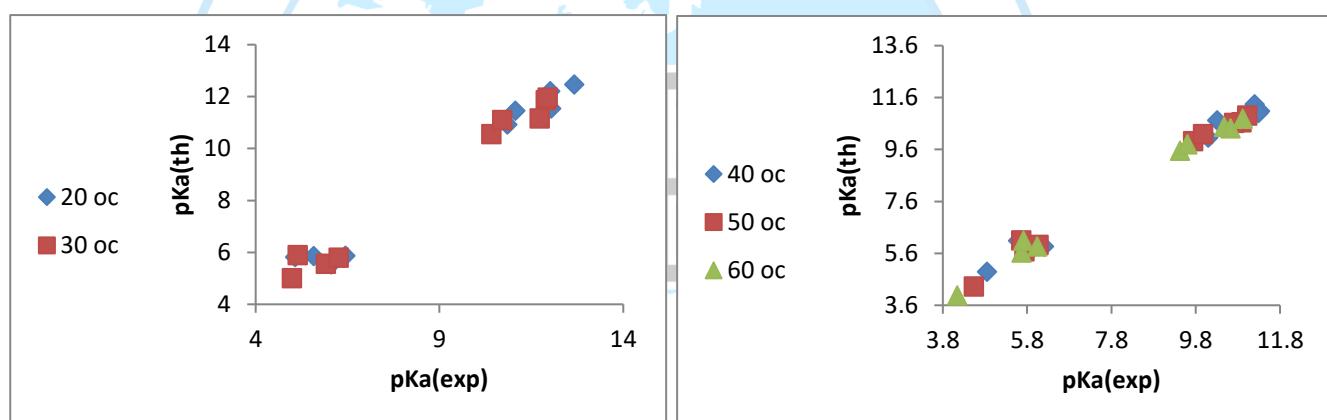

Figure (2): Relation between experimental [9] and calculated pKa values

Table (15): Variation of parameters with increasing temperature and improving the R^2 and SE.

T °C	Parameter	R ²	SE
20	TE L _{NH2} L _{OH}	0.979	0.589
30	TE M _{NH2} M _{OH}	0.982	0.542
40	TE N _L C=N	0.988	0.381
50	TE N _L Dipol2	0.993	0.289
60	TE N _L Dipol2	0.994	0.251

This improvement in the values of R^2 and SE from 20-60°C could be attributed to the freedom acquired by the molecules as a results of destruction of physical forces between solvent and

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

Ra'ed T. Gh. Al-Abady, Fedaa Hasan Meire Altaiea and Emad A. S. Al-Hyali

considered Schiff bases, among the solvents molecules (C_2H_5OH) and among the studied molecules themselves. At 20 and 30°C the Lowdin and Mullikan charge of N and O atoms in NH_2 and OH charges (L_{NH_2} , L_{OH} , M_{NH_2} , M_{OH}) with the TE were dominant. While at 40°C, the dependence on the charge decreased and the length of azo imine bond (C=N) started to appear in parameter which may due to the increase of the charge movement across the two aromatic rings in the studied molecules. The increasing of temperature into 50 and 60. The correlation between the calculated and experimental pKa became more consistent, a new parameters appeared in the regression analysis (Dipol2) which is indicated to the increase of charge separation across the Schiff base collected for this study with increasing temperature due to breaking down of all physical forces. Separation of the charges leading to formation of dipoles on the rings. This is supported by the increase of R^2 to be more close to unity and raising the consistency between the experimental and calculated pKa values to less than 5%, of the accepted experimental error.

Evaluation of thermodynamic functions

The thermodynamic functions are valuable parameters. Their study and estimation are very important since they give good indications about the favored direction of the ionization process of the Schiff bases and the type of forces controlling the ionization process due the acquiring or releasing temperature throughout the ionization process and the order of studied system. In order to calculate, ΔG° , ΔH° , ΔS° . The values of ΔG° is estimated at equilibrium and when K is determined at various temperatures by equation(8) [15,16].

$$\Delta G^\circ = -nRT \ln K = nRT pK_a \dots \dots \dots (8)$$

$$\text{sin c e } pK_a = -\ln K_a \dots \dots \dots (9)$$

$$\ln K_a = \frac{-\Delta G^\circ}{RT}, \Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

$$\ln K_a = \frac{-(\Delta H^\circ - T\Delta S^\circ)}{RT} = \frac{-\Delta H^\circ}{RT} + \frac{\Delta S^\circ}{R} \dots \dots \dots (10)$$

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

Ra'ed T. Gh. Al-Abady, Fedaa Hasan Meire Altaiea and Emad A. S. Al-Hyali

According to Van't Hoff (Eq. 10) The plot of $\ln K_a$ versus $\frac{1}{T}$ should give straight line with slope

equal to $-\frac{\Delta H^\circ}{R}$ and intercept $\frac{\Delta S^\circ}{R}$ (Fig. 3).

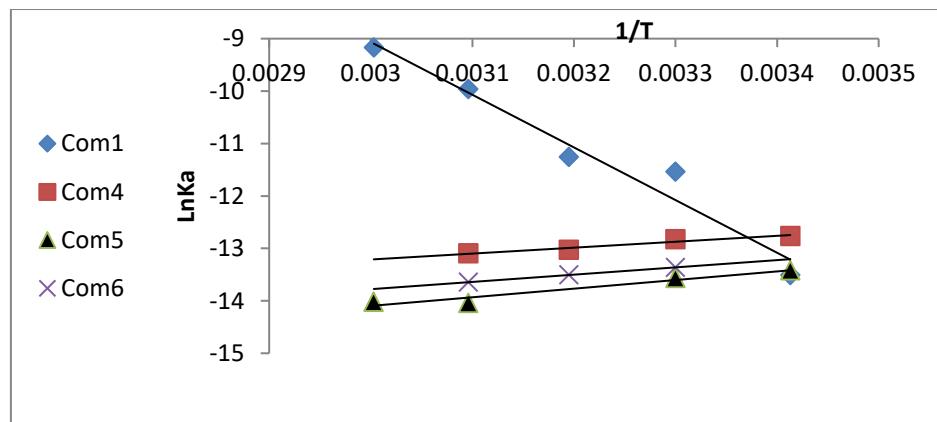

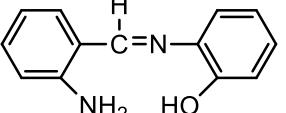

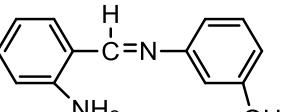

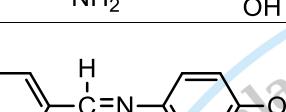

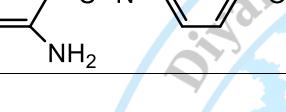

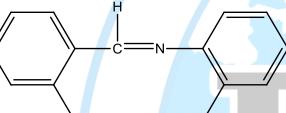

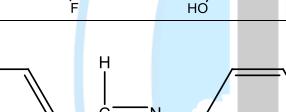

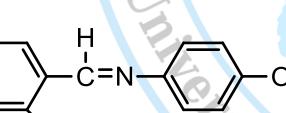

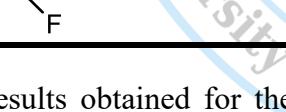

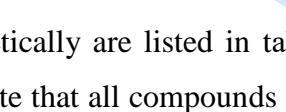

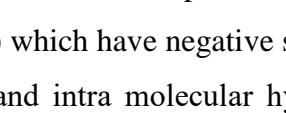

Figure (3): Application of Van't Hoff equation on the calculated K_a to estimate the thermodynamic functions theoretically.

	-22.5608	333	62.460		48.802

The results obtained for the calculation of the thermodynamic functions (ΔG° , ΔH° and ΔS°) theoretically are listed in table (16). The sign and values of the variation in the enthalpy ΔH° indicate that all compounds are endothermic indicated by the positive sign except (comp.No.4,5, and 6) which have negative sign representing exothermic reaction. This could be attributed to the inter and intra molecular hydrogen bonding which are assigned by the values of ΔH° (9-18) KJ.mol⁻¹. Other compounds are endothermic and need additional heat to start the ionization process of the compounds under consideration. This is supported by non-spontaneous reaction (positive value of ΔG°). The spontaneity increases (ΔG° became less) with increasing temperatures

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

Ra'ed T. Gh. Al-Abady, Fedaa Hasan Meire Altaiea and Emad A. S. Al-Hyali

except for the (comps 4-6) in which the spontaneity decreases (ΔG° increasing as a positive values) with increasing temperature. Looking at the entropy values, the positive values indicating into the disorder of studied system except (comp 4,5,6 and 8) which pointing out to increasing the order of system indicated by the negative values of the ΔS° which may indicate to the increasing of order of the system considered. Values of ΔH of comp (4,5,6 and 8) KJ.mol^{-1} (less than 40 KJ.mol^{-1}) where as other compounds showed chemical bonds. The value of ΔS° of comp. 4,5,6 and 8 showed more ordered system indicated by negative values and the rest of the compounds showed increasing disorder indicated by the positive sign of ΔS° obtained [12,13].

Conclusion

The above discussion so far showed very good consistency between the practical and theoretically calculated values conducted in this study. The strength of consistency between each two of the considered parameters are evaluated in terms of R^2 . Simple regression analysis is used for estimation of this consistency. The relation between the calculated and experimental thermodynamic functions, $p\text{Ka}(\text{calc})$ and $p\text{Ka}(\text{exp})$, and $\Delta G^\circ(\text{exp})$ and $\Delta G^\circ(\text{calc})$ to the $p\text{Ka}(\text{exp})$ values [9]. The results of these correlations are listed in Table (17).

Table (17): Simple regression analysis used to find relations between thermodynamic functions, $p\text{Ka}(\text{calc})$ and $p\text{Ka}(\text{exp})$, and $\Delta G^\circ(\text{exp})$ [9]

parameter	$p\text{Ka}(\text{exp})$	$p\text{Ka}(\text{calc})$	$\Delta G^\circ(\text{exp})$	$\Delta G^\circ(\text{calc})$
$p\text{Ka}(\text{exp})$	1.000			
$p\text{Ka}(\text{calc})$	0.993	1.000		
$\Delta G^\circ(\text{exp})$	0.886	0.877	1.000	
$\Delta G^\circ(\text{calc})$	0.982	0.989	0.883	1.000

Looking at table (17) shows good correlation between $p\text{Ka}(\text{exp})$ and $p\text{Ka}(\text{calc})$ ($R=0.993$), the relation between $\Delta G^\circ(\text{calc})$ and $p\text{Ka}(\text{calc})$ ($R=0.989$), and between $\Delta G^\circ(\text{calc})$ and $\Delta G^\circ(\text{exp})$ (0.883). The $\Delta G^\circ(\text{calc})$ and $\Delta G^\circ(\text{exp})$ are in good agreement in their values and in the physical meaning.

Determination Of Thermodynamic Functions from the pKa Values of a Number of Schiff Bases by Employing the DFT Method: Theoretical Study

Ra'ed T. Gh. Al-Abady, Fedaa Hasan Meire Altaiea and Emad A. S. Al-Hyali

This method has proved so far to be applicable to such calculations and the DFT as a good choice for such applications.
